Hence, the probability in question, which equals the number of favourable outcomes divided by the number of possible outcomes, is given by the binomial distribution. where $p = r / (r + b)$ and $q = b / (r + b) = 1 - p$. For example, suppose $r = 2$ b and $n = 4$.

That means that $P(A \cup B) = P(A) + P(B) - P(A \cap B)$ where the last equality is because, as we said above, the probability of a continuous RV taking on exactly one particular value, as it would in events $\{A\}$ and $\{B\}$, is $\{0\}$. The same would be true if we added merely one endpoint of the interval $\{[a, b)\}$. To summarize: FACT 4.3.17.

For aesthetic, strategic and pragmatic reasons, Jaynes (Probability: The Logic of Science, Cambridge University Press, Cambridge, 2003, Appendix A) objects to Bruno de Finetti's founding of probability theory on the basis of the notion of coherence. In this paper an attempt is made to diffuse this critique, as well as to point out, briefly, that these, and the remarks on a variety of ...

de Finetti's theory of probability and its Jaynesian critique
The word probability derives from the Latin probabilitas, which can also mean "probrity", a measure of the authority of a witness in a legal case in Europe, and often correlated with the witness's nobility.in a sense, this differs much from the modern meaning of probability, which, in contrast, is a measure of the weight of empirical evidence, and is arrived at from inductive reasoning and ...
